*Near Field Emission Scanning Electron Microscopy* Taryl Leaton Kirk, 2010 Low beam energies have been implemented in a simplified SEM technique where the electron source remote in standard SEMs is brought within tens of nanometers to the object This method known as the near field emission scanning electron microscopy NFESEM is capable of imaging conducting surfaces with nanometer resolution using beam energies less than 60 eV The terminology near refers to the locality of the field emitted electron source which is to distinguish itself from the remote field emission gun sources used in standard SEMs The main aim of this instrument is the realization of some kind of surface topography image due to the exposure of a primary beam of electrons as it is rastered along the sample surface This will be achieved by two distinct although related experiments measuring the field emission FE current while scanning and detecting the secondary electrons SE's generated when the electron beam impinges on the surface Here the FE properties in accordance with the tip sample separation will be emphasized since the variations in SE yield are directly proportional to the impinging primary electron

beam We observe a direct correlation between the image contrast and the FE current where the image is enhanced with increasing FE current Moreover simple electrostatic measurements can be used to define the performance of the device
