Processing Guangji Shi, 2006 The performance of automatic speech recognition ASR systems degrades significantly in adverse environments due to ambient noise and reverberation This problem becomes even greater in hands free speech applications where the microphones can be placed far away from the speaker of interest Environmental robustness has become a major barrier that prevents ASR from a wide range of applications such as voice recognition in a car and voice controlled hand held devices In this research the importance of phase in robust speech recognition is explored First the effect of phase uncertainty on the recognition accuracy of human listeners is investigated The goal is to get a quantitative measure on the importance of phase The results show that the importance of phase varies with SNR signal to noise ratio At low SNR conditions phase can have a significant impact on speech recognition accuracy Next motivated by the importance of phase in multi microphone signal processing a phase based dual microphone noise masking approach is proposed for speech enhancement By utilizing the time delay of the speech source of interest to the two microphones and the actual phases of the signals recorded by both microphones the algorithm filters the noise signal in the short time Fourier transform domain By doing so the noise components are distorted beyond recognition and the speech recognition accuracy is improved The effectiveness of this approach is demonstrated through performance comparison with alternative techniques Lastly an automatic parameter estimation technique is developed to further optimize its performance The parameter of the phase based dual microphone filter is adjusted in run time automatically by performing likelihood calculations of the enhanced speech features using a prior speech model Speech recognition tests show that this adaptive approach not only achieves better recognition accuracy but also improves the filter s robustness when time delay estimates are inaccurate Phase

Spectrum Based Speech Processing and Spectral Energy Estimation for Robust Speech Recognition Anthony Stark, 2011

Abstract Speech is the dominant mode of communication between humans simple to learn easy to use and integral for modern life Given the importance of speech development of a human machine speech interface has been greatly anticipated This challenging task is encapsulated in the digital speech processing research field In this dissertation two specific areas of research are considered 1 the use of short time Fourier spectral phase in digital speech processing and 2 use of the minimum mean square error spectral energy estimator for environment robust automatic speech recognition In speech processing and modelling the short time Fourier spectral phase has been considered of minor importance This is because classic psychoacoustic experiments have shown speech intelligibility to be closely related to short time Fourier spectral magnitude Given this result it is unsurprising that the majority of speech processing literature has involved exploitation of the short time magnitude spectrum Despite this recent studies have shown useful information can be extracted from the spectral phase of speech As a result it is now known that spectral phase possesses much of the same intelligibility information as spectral magnitude It is this avenue of research that is explored in greater detail within this dissertation In particular we investigate two phase derived quantities u2013 the short time instantaneous frequency spectrum and the short time group delay spectrum The properties of both spectra are investigated mathematically and empirically identifying the relationship between known speech features and the underlying phase spectrum We continue the investigation by examining two related quantities u2013 the instantaneous frequency deviation and the group delay deviation As a result of this research two novel phase based spectral representations are proposed both of which show a high degree information applicable to speech processing
