

CHEM 155: BASIC PHYSICAL CHEMISTRY I

INTRODUCTION

Physical chemistry is the study of the fundamental physical principles that govern the way that atoms, molecules, and other chemical systems behave. Physical chemists study a wide array of phenomena such as the rates of chemical reactions (kinetics), the way that light and matter interact (spectroscopy), how electrons are arranged in atoms and molecules (quantum chemistry), and the stabilities and reactivities of different compounds and processes (chemical thermodynamics).

The goal of physical chemistry is to develop mathematical models that explain and predict the structures of molecules and the forces that govern the behavior of chemical reactions. Through the results of physical chemistry, a synthetic chemist can calculate, before pouring the potions together, what would react – or overreact – and how much heat would be required or produced, knowledge that could spell the difference between rocket liftoff and launch pad disaster. Using the tools of physical chemistry, a biochemist can build a model of a biological molecule, such as the enzyme the HIV virus uses to copy itself, and predict the shape of a molecule that would block its function and prevent HIV replication.

The theory of physical chemistry is what enables us to determine the power of explosions, the composition of clouds, and the structures of particles millions of times smaller than the point of a pin. We use physical chemistry to decide the metabolism of dinosaurs, the makeup of stars, and the rates of reactions within the living cell.

Physical chemistry began with attempts to understand reactions wielded by alchemists and progressed by the use of mathematics and physics to comprehend and control what was
