Preventing Disasters: The Grand Challenge for Earthquake Engineering Research

THE EARTHQUAKE HAZARD

Earthquakes occur as a result of sudden displacements across a fault within the earth. The earthquake releases part of its stored strain energy as seismic waves. These waves propagate outward and along the earth's surface. It is the motion of the ground as these waves move past that is perceived as an earthquake. With most earthquakes, ground shaking is the direct and principal cause of damage to buildings and infrastructure. Considerable damage can be caused by fault rupture at the surface, but this is generally limited to places near the fault. Sometimes indirect shaking effects such as tsunamis, landslides, fire caused by gas-line breaks, and flooding caused by water-line breaks also play a significant role.

Although fewer than 150 lives have been lost in the United States since 1975 as a result of earthquakes (Cutter, 2001), the potential for economic loss and social disruption is enormous (Mileti, 1999). Recent California earthquakes of even moderate magnitude, such as the Loma Prieta earthquake in 1989 and the Northridge earthquake in 1994, caused damage ranging up to \$30 billion (Sidebar 1.1). While the seismic risk is highest in California, other regions as geographically dispersed as western Washington state, Alaska, Utah, South Carolina, the midcontinent, and areas around Boston, the St. Lawrence Seaway, and New York City all have significant potential for earthquake-related damage and economic loss. Studies conducted by the U.S. Geological Survey demonstrate that except for Texas, Florida, the Gulf Coast, and the upper Midwest, most of the United States is at some risk from earthquakes (USGS, 2002).
