Medical research frequently employs studies where the outcome/dependent variable is monitored or assessed repeatedly over different time points among the same study participants. Such repeatedly measured outcome over time are referred to as longitudinal data.

In a **longitudinal study**, participant's outcomes and possibly treatments or exposures are collected at multiple follow-up times (**on the same set of participants**). For e.g., in a group of HIV patients, every month their CD4 count or viral load is monitored.

Properties of Longitudinal study design:

1. Having repeated observations on individuals allows for studying the change in the outcome over time.
2. Can be used to assess both the changes in the outcome over time within individuals and between the individuals.
3. Use of sophisticated data statistical techniques because the repeated observations are usually correlated.
4. Since certain types of correlation structures are likely to arise from longitudinal data, correlation must be accounted to obtain valid inference.
5. Study participants act as their own control which economizes on participants and reduces unexplained variability in the response.

6. Handles missing data and irregularly spaced measurement robustly (only if Mixed effect modeling was used)
7. The dataset used for analyzing the effect of repeated observations on the outcome of interest should be in a **long format**.

In this article, we review the different statistical techniques used for analyzing longitudinal data with the help of research questions.

There are different types of longitudinal studies:

1. Panel study: Longitudinal follow up of subjects over a period of time, repeated measurements. Panel can be at the level of household or at individual level. E.g.: Longitudinal Ageing Study in India (LASI) – household panel study
2. Cohort study: A group of people with similar characteristics will be followed up over a period of time. E.g.: Indian Migration study.
3. Trials- RCT, Pre/ Post interventions

Different Modelling strategies used in the analysis of longitudinal data in which the outcome variable is a continuous variable are:

Traditional Methods:

1. Repeated-measures ANOVA
